CS 4910: Intro to Computer Security

Chapter 1: Overview

Instructor: Xi Tan

Updates

Environment Setup

- SEED Labs 2.0: <u>https://seedsecuritylabs.org/Labs_20.04/</u>
- Environment Setup: <u>https://seedsecuritylabs.org/labsetup.html</u>
- Lab Setup: https://seedsecuritylabs.org/labsetup.html
 - Choose Ubuntu 20.04 VM.
 - The pre-built SEED VM

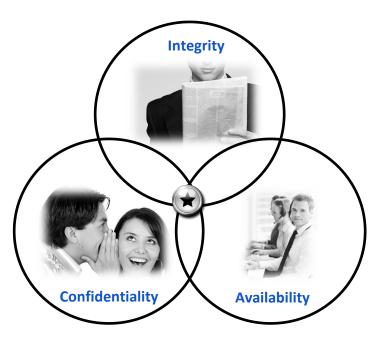

What is computer security?

What is Computer Security

The NIST Internal/Interagency Report NISTIR 7298 (Glossary of Key Information Security Terms , May 2013) Defines the Term Computer Security as Follows:

"Measures and controls that ensure confidentiality, integrity, and availability of information system assets including hardware, software, firmware, and information being processed, stored, and communicated."

Security Objectives (CIA Triad)

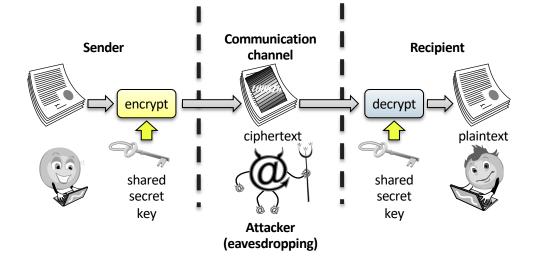

Confidentiality

Confidentiality: Prevent/detect/deter unauthorized disclosure of information.

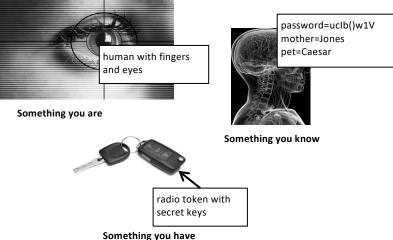

- Data confidentiality : Assures that private or confidential information is not made available or disclosed to unauthorized individuals.
- Privacy : Assures that individuals control or influence what information related to them may be collected and stored and by whom and to whom that information may be disclosed.

• Encryption: the transformation of information using a secret, called an encryption key, so that the transformed information can only be read using another secret, called the decryption key

- Access control / Authorization : rules and policies that limit access to confidential information to those people and/or systems with a "need to know."
 - This need to know may be determined by identity, such as a person's name or a computer's serial number, or by a role that a person has, such as being a manager or a computer security specialist.
 - The determination if a person or system is allowed access to resources, based on an access control policy.
 - Such authorizations should prevent an attacker from tricking the system into letting him have access to protected resources.

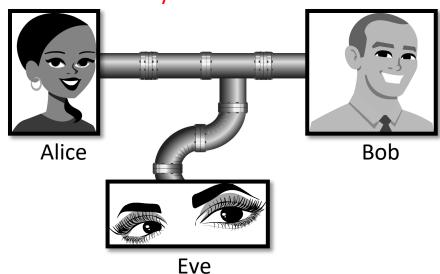

- Authorization : the determination of the identity or role that someone has. This determination can be done in a number of different ways, but it is usually based on a combination of
 - something the person has (like a smart card or a radio key fob storing secret keys),
 - something the person knows (like a password),
 - something the person is (like a human with a fingerprint).

- **Physical security:** the establishment of physical barriers to limit access to protected computational resources.
 - Such barriers include locks on cabinets and doors, the placement of computers in windowless rooms, the use of sound dampening materials, and even the construction of buildings or rooms with walls incorporating copper meshes (called Faraday cages) so that electromagnetic signals cannot enter or exit the enclosure.

Examples

- **Eavesdropping:** the interception of information intended for someone else during its transmission over a communication channel.
 - Example: packet sniffers
 - This is an attack on confidentiality

Integrity

Integrity: Prevent/detect/deter **improper modification** of information

- Data integrity : Assures that information and programs are changed only in a specified and authorized manner.
- System integrity : Assures that a system performs its intended function in an unimpaired manner, free from deliberate or inadvertent unauthorized manipulation of the system.

Tools for Integrity

•

Backups: the periodic archiving of data.

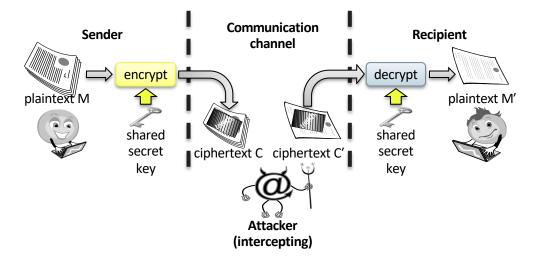

Checksums: the computation of a function that maps the contents of a file to a numerical value. A checksum function depends on the entire contents of a file and is designed in a way that even a small change to the input file (such as flipping a single bit) is highly likely to result in a different output value.

Data correcting codes: methods for storing data in such a way that small changes can be easily detected and automatically corrected.

Examples

- Alteration: unauthorized modification of information.
 - **Example:** the **man-in-the-middle attack**, where a network stream is intercepted, modified, and retransmitted.
 - This is an attack on data integrity

Availability

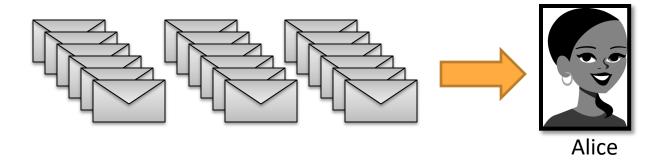

Availability: Prevent/detect/deter improper denial of access to services provided by the system

Tools:

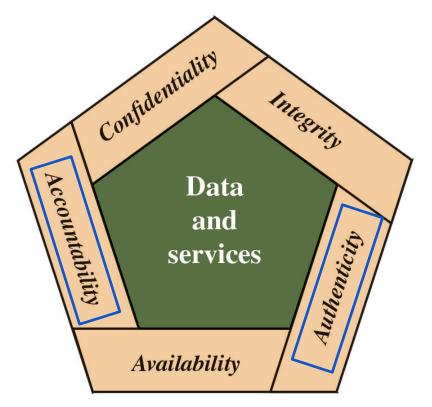

- **Computational redundancies**: computers and storage devices that serve as fallbacks in the case of failures
- **Physical protections**: infrastructure meant to keep information available even in the event of physical challenges.

Examples

- **Denial-of-service:** the interruption or degradation of a data service or information access.
 - **Example:** email **spam**, to the degree that it is meant to simply fill up a mail queue and slow down an email server.
 - This is an attack on availability

In Addition to CIA Triad

In Addition to CIA Triad

- Authenticity: The assurance that a message, transaction, or other exchange of information is from the source it claims to be from.
- Primary tool:
 - Digital signatures. These are cryptographic computations that allow a person or system to commit to the authenticity of their documents in a unique way that achieves nonrepudiation, which is the property that authentic statements issued by some person or system cannot be denied.

Examples

- **Masquerading:** the fabrication of information that is purported to be from someone who is not actually the author.
 - Example: **phishing** (BankofAmarica.com looks like BankofAmerica.com), **spoofing** (Send a network packet the wrong return IP address)
 - This is an attack on authenticity

"From: Alice" (really is from Eve)

In Addition to CIA Triad

- Accountability: The security goal that generates the requirement for actions of an entity to be traced uniquely to that entity.
- Example: Data Breach in a Healthcare Organization
 - A large healthcare organization holds sensitive medical records of millions of patients. Due to lax security measures, an unauthorized individual gains access to their database and downloads confidential patient data, which includes names, medical histories, and social security numbers.
 - This is an attack on accountability

Authentication vs Authorization

- Authentication Who goes there?
 - Restrictions on who (or what) can access system
- Authorization Are you allowed to do that?
 - Restrictions on actions of authenticated users
 - Authorization is a form of **access control**

How to we achieve the objectives? What are the possible measures and controls?

The means of achieving these objectives greatly differ

- cryptographic techniques
- access control policies
- software checking tools
- virus scanners
- firewalls
- spam filters, etc.

Each system must be evaluated uniquely in terms of its requirements

security mechanisms must be adequately chosen in accordance with those requirements

Levels of Impact

• Low

• The loss could be expected to have a limited adverse effect on organizational operations, organizational assets, or individuals

- Moderate
 - The loss could be expected to have a serious adverse effect on organizational operations, organizational assets, or individuals
- High

• The loss could be expected to have a severe or catastrophic adverse effect on organizational operations, organizational assets, or individuals

Why is Computer Security Hard?

• Identifying security requirements of a system is non-trivial

O must take into account services, environment, etc.

- Finding adequate (often complex) solutions is not easier
 - O the decision must take into account known and unknown attacks and threats
 - O security mechanisms must be logically placed
- Securing a system is not a one-time task
 - the system must be constantly monitored in face of changing threats
 - O security mechanisms need to be re-evaluated

Why is Computer Security Hard?

- Managers do not perceive value in security investment (until a security failure occurs)
 - system administrators might not influence decisions or not make good decisions
- Users view security measures as an obstacle on the way of getting their work done
 - we would like security mechanisms to be as intuitive and robust as possible
- Adding security to an existing system might not be pretty
 - ideally, security is an integral part of the design

Computer Security Terminology (1 of 3)

Adversary (threat agent)

 Individual, group, organization, or government that conducts or has the intent to conduct detrimental activities.

Attack

• Any kind of malicious activity that attempts to collect, disrupt, deny, degrade, or destroy information system resources or the information itself.

Countermeasure

• A device or technique that has as its objective the impairment of the operational effectiveness of undesirable or adversarial activity, or the prevention of espionage, sabotage, theft, or unauthorized access to or use of sensitive information or information systems.

Computer Security Terminology (2 of 3)

Risk

• A measure of the extent to which an entity is threatened by a potential circumstance or event, and typically a function of 1) the adverse impacts that would arise if the circumstance or event occurs; and 2) the likelihood of occurrence.

Security Policy

• A set of criteria for the provision of security services. It defines and constrains the activities of a data processing facility in order to maintain a condition of security for systems and data.

System Resource (Asset)

• A major application, general support system, high impact program, physical plant, mission critical system, personnel, equipment, or a logically related group of systems.

Computer Security Terminology (3 of 3)

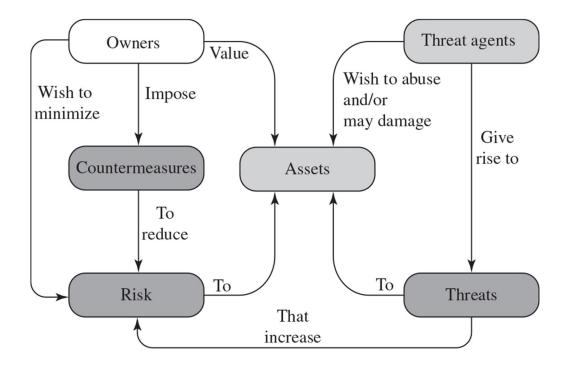

Threat

• Any circumstance or event with the potential to adversely impact organizational operations (including mission, functions, image, or reputation), organizational assets, individuals, other organizations, or the Nation through an information system via unauthorized access, destruction, disclosure, modification of information, and/or denial of service.

Vulnerability

• Weakness in an information system, system security procedures, internal controls, or implementation that could be exploited or triggered by a threat source.

Security Concepts and Relationships

Assets of a Computer System

Hardware

Software

Data

Communication facilities

and networks Local and wide area network communication links, bridges, routers, etc.

Data storage, data communication devices, etc.

Operating system, system utilities, and applications. Files and databases, security-related data/password files.

Vulnerabilities, Threats and Attacks

- Categories of vulnerabilities
 - Corrupted (loss of integrity)
 - Leaky (loss of confidentiality)
 - Unavailable or very slow (loss of availability)

Vulnerabilities, Threats and Attacks

• Threats

- Capable of exploiting vulnerabilities
- Represent potential security harm to an asset

Vulnerabilities, Threats and Attacks

Attacks (threats carried out)

- passive: observes information without intervention
 - e.g., passively monitoring a communication link
- active: alters system resources or affects their operation
 - e.g., changing messages, replaying old messages on the network, corrupting users, etc.
- insider: is legitimately a part of the system with access to internal data or is inside the security perimeter
- outsider: is outside of the security perimeter or is not a legitimate user

Countermeasures

- Means used to deal with security attacks
 - o Prevent
 - o Detect
 - o Recover
- May itself introduce new vulnerabilities
- Residual vulnerabilities may remain
- Goal is to minimize residual level of risk to the assets

Computer and Network Assets, with Examples of Threats

Blank	Availability	Confidentiality	Integrity
Hardware	Equipment is stolen or disabled, thus denying service.	An unencrypted USB drive is stolen.	A door sensor is replaced with one that sends a closed status, regardless of actual door position, at certain times.
Software	Programs are deleted, denying access to users.	An unauthorized copy of software is made.	A working program is modified, either to cause it to fail during execution or to cause it to do some unintended task.
Data	Files are deleted, denying access to users.	An unauthorized read of data is performed. An analysis of statistical data reveals underlying data.	Existing files are modified or new files are fabricated.
Communica-tion Lines and Networks	Messages are destroyed or deleted. Communication lines or networks are rendered unavailable.	Messages are read. The traffic pattern of messages is observed.	Messages are modified, delayed, reordered, or duplicated. False messages are fabricated.

Passive and Active Attacks

Passive Attack

- Attempts to learn or make use of information from the system, but it does not affect system resources
- Eavesdropping on, or monitoring of, transmissions
- Goal of attacker is to obtain information that is being transmitted
- Two types:
 - Release of message contents
 - Traffic analysis

Active Attack

- Attempts to alter system resources or affect their operation
- Involve some modification of the data stream or the creation of a false stream
- Four categories:
 - O Replay
 - O Masquerade
 - O Modification of messages
 - O Denial of service

Security Design Principles

- economy of mechanism
- open design, modularity
- layering
- complete mediation
- fail-safe defaults
- separation of privilege, least privilege
- least common mechanism
- psychological acceptability, least astonishment
- isolation, encapsulation

Attack Surfaces

- Consist of the reachable and exploitable vulnerabilities in a system
- Examples:
 - Open ports on outward-facing Web and other servers, and code listening on those ports
 - Services available on the inside of a firewall
 - Code that processes incoming data, email, XML, office documents, and industryspecific custom data exchange formats
 - Interfaces, SQL, and Web forms
 - An employee with access to sensitive information that is vulnerable to a social engineering attack

Attack Surface Categories

Network Attack Surface

- Vulnerabilities over an enterprise network, wide-area network, or the Internet
- Included in this category are network protocol vulnerabilities, such as those used for a denial-of-service attack, disruption of communications links, and various forms of intruder attacks

Software Attack Surface

- Vulnerabilities in application, utility, or operating system code
- Particular focus is Web server software

Human Attack Surface

 Vulnerabilities created by personnel or outsiders, such as social engineering, human error, and trusted insiders

Computer Security Strategy (1 of 2)

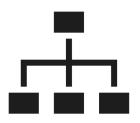

Security Policy

Security Implementation

Formal statement of rules and practices that specify or regulate how a system or organization provides security services to protect sensitive and critical system resources Involves four complementary courses of action:

- Prevention:
- Detection
- Response
- Recovery

Computer Security Strategy (2 of 2)

Assurance

Evaluation

Encompassing both system design and system implementation, assurance is an attribute of an information system that provides grounds for having confidence that the system operates such that the system's security policy is enforced Process of examining a computer product or system with respect to certain criteria

Involves testing and may also involve formal analytic or mathematical techniques

Summary of Chapter 1

- Computer security concepts
 - Definition: CIA
 - Challenges
 - o Model
- Threats, attacks, and assets
 - Threats and attacks
 - Threats and assets

- Fundamental security design principles
- Attack surfaces and attack trees
 - Attack surfaces
 - Attack trees
- Computer security strategy
 - Security policy
 - Security implementation
 - Assurance and evaluation

Takeaways

- Security is not absolute
 - assets can have different security grades depending on the impact of a security breach that can range from low to high
 - by building more secure systems, we make it harder for an attacker to breach security
 - the more resources we can invest in a system, the more secure we can make it
 - there is a trade-off between security and resources (money, equipment, personnel, training)
 - training must cover all users, as security can often be easiest breached by exploiting human error
